

**Antibacterial Resistance Leadership Group (ARLG)**

# **Fast Antibiotic Susceptibility Testing for Gram-Negative Bacteremia (FAST) Trial**

**8<sup>th</sup> Annual Texas Medical Center Antimicrobial Resistance and Stewardship Conference: Jan 16, 2025**

**Principal Investigator – Ritu Banerjee, MD, Ph.D**

# We need faster blood culture diagnostics

- **Sepsis due to bloodstream infections**
  - 30% mortality with ineffective treatment
  - \$15 billion in hospital costs (US)
- **Blood cultures**
  - Organism ID and antimicrobial susceptibility testing (AST) results >2 days AFTER a positive culture
- **Early treatment** is critical but empiric
  - Ineffective = poor outcomes
  - Overtreatment = drug resistance, AEs

# Background Study– RApid IDentification and Susceptibility testing for Gram Negative bacteremia (RAPIDS GN) trial

- **Hypothesis:** Rapid *phenotypic* AST methods enable optimal management of GN bacteremia
- **Multicenter, prospective RCT** in 2 US sites to evaluate antibiotic use and outcomes among patients with **GNB bacteremia** who have blood culture evaluated using standard methods vs. rapid ID/AST
- Randomized to either:
  - Standard culture and AST (SOC) [N=226] or
  - Rapid identification and AST using Pheno System (Accelerate Diagnostics) and SOC [N=222]
- Both arms had antibiotic stewardship review
- Primary outcome: Time to antibiotic change

# Results from RAPIDS GN

## Antibiotic changes vary by testing method and resistance

### Time to GN antibiotic change

### Time to abx escalation

### Time to abx de-escalation

— Standard of care method  
— RAPID method

— Resistant isolate  
- - - Susceptible isolate

## Conclusions from RAPIDS GN

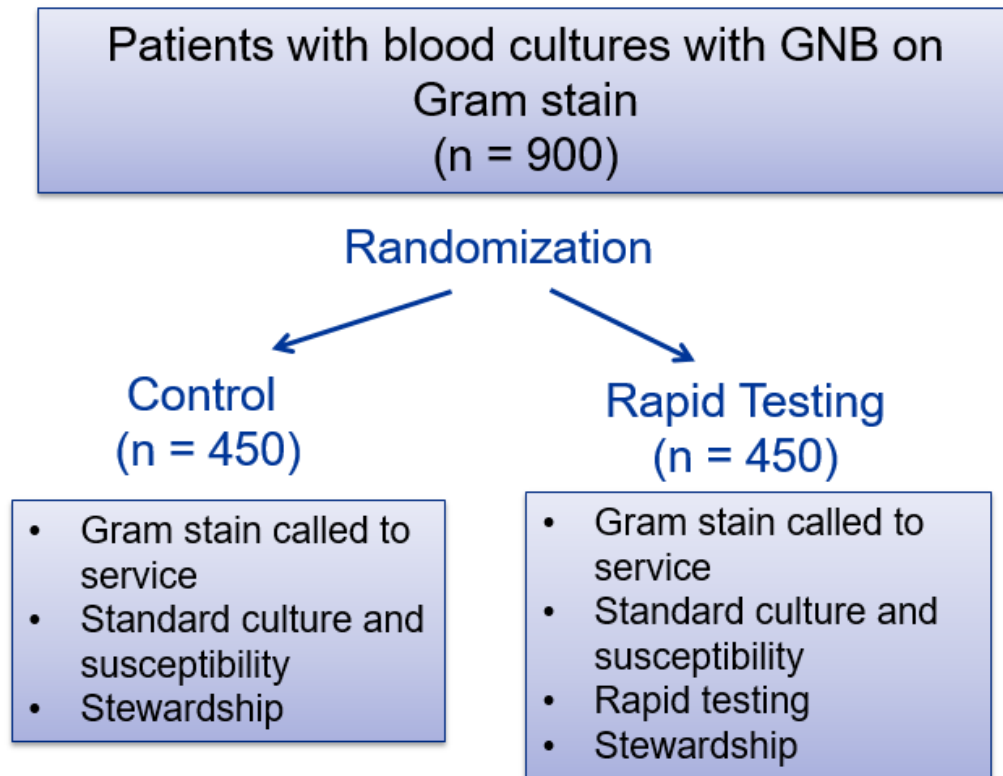

- Rapid *phenotypic* AST methods implemented with stewardship can optimize treatment of GNB bloodstream infections
- Antibiotic modifications occurred **faster with rapid testing** than SOC
- **Limitations:**
  - **Not powered to detect differences in clinical outcomes**
  - **Low rates of MDR GNB**
  - **Costly rapid AST method**

# Fast Antibiotic Susceptibility Testing for Gram-negative bacteremia (FAST)

- **Hypothesis:** Rapid *phenotypic* AST methods implemented with stewardship can optimize treatment and improve outcomes of GNB bloodstream infections
- **Objective:** To compare **clinical outcomes** among patients with GNB BSI who have isolate AST determined using rapid AST method (VITEK Reveal™) vs. SOC methods *in areas with high resistance rates*

# Multisite, multinational, prospective RCT

- Participants with Gram-negative bacilli (GNB) bloodstream infection will be randomized to either:
  - Standard culture and AST (SOC) or
  - Rapid AST in addition to SOC
- Both arms will receive stewardship consultation per SOC
- Enroll 900 patients with GN BSI

# Rapid Metabolomic-Based AST: VITEK REVEAL™

- Approved in Europe *and US*
- Measures changes in volatile organic compounds emitted during bacterial growth
- Mean TAT ~5 hours
- Does not provide ID

# Eligibility Criteria

## ■ Inclusion criteria

- Positive blood culture with Gram stain showing GNB
- Hospitalized at the time of randomization

## ■ Exclusion criteria

- Positive blood culture for GNB within prior 7 days (if known at time of randomization)
- Deceased at time of randomization
- Gram-positive bacilli, Gram-negative cocci, multiple morphologies of GNB, and/or yeast detected on Gram stain of blood culture
- Previous enrollment in this study

# Endpoints

## ■ Primary – Desirability Of Outcome Ranking (DOOR) at 30 days

- Alive no deleterious events
- Alive with 1 to 3 deleterious events
- Death

### Deleterious Events include any of the following

<u>Unsuccessful discharge:</u>	<u>Lack of clinical response:</u>	<u>Undesirable events</u>
<ul style="list-style-type: none"> <li>• Not discharged from index hospitalization</li> <li>• Readmission</li> </ul>	<ul style="list-style-type: none"> <li>• Relapse of bacteremia with the same species causing the index infection</li> <li>• Local suppurative complications not present at randomization</li> <li>• Seeding distant sites with infecting organism after randomization</li> </ul>	<ul style="list-style-type: none"> <li>• <u>Acquisition of hospital-acquired infection</u> <ul style="list-style-type: none"> <li>– <i>C. difficile</i></li> <li>– Multidrug resistant organisms (MDROs)</li> </ul> </li> <li>• <u>Post-randomization renal failure defined by RIFLE criteria:</u> <ul style="list-style-type: none"> <li>– Three-fold or greater increase in serum creatinine</li> <li>– New renal replacement therapy</li> </ul> </li> </ul>

## ■ Secondary

- All-cause in-hospital mortality up to 30d
- LOS in hospital and ICU up to 30d
- Acquisition MDRO/*C. difficile* up to 30d
- Time to abx modification in the first 72h
- Time to effective antibiotic treatment within 72h

## ■ Exploratory

- Discrepancies between REVEAL and SOC
- Changes in antibiotics that match at least one AS recommendation
